Beirut – 6<sup>th</sup> & 7<sup>th</sup> December 2018

# Energetic Situation in Tunisia

## Evolution of Energy Balance

Source : ONE

# Energetic Situation in Tunisia

## Energy Subsidies

Governmental direct subsidies for energy sector

The global subsidies in 2013:  $\approx 5300$  MTND,

- 43% are allocated for oil products,
- **41% for electricity,**
- 16% for natural gas,
- 0.9% for energy conservation.

# Energetic Situation in Tunisia

## Evolution of Electricity demand

Evolution of the net national electricity demand 1985 – 2016

Rate of annual growth of electricity demand during the last three decades:  $\approx 5\%$ .  
National electricity demand In 2016: 15079 GWh

# Energetic Situation in Tunisia

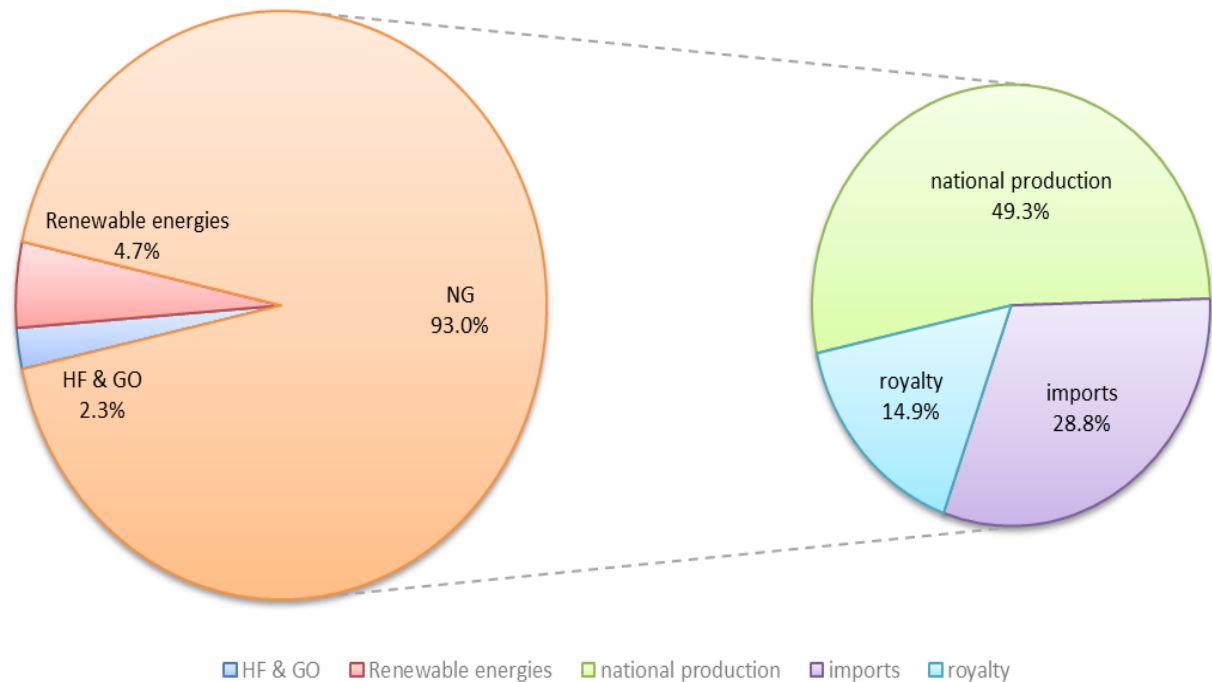

## Electricity Mix

Evolution of the Electricity Mix

# Energetic Situation in Tunisia

## Electricity Mix

Primary energy utilisation for electricity production in 2014

Dependency on fossil fuels (Natural Gaz)

# Energetic Situation in Tunisia

## Main characteristics

- Big deficit in the primary energy balance
- Large amount of subsidies ( $\approx 5300$  MTND in 2013)
- High level of electricity demand (15079 GWh in 2016) and high rate of growth (5%)
- Electricity Mix based on fossil fuels (93% NG)

Need for energy transition

- More Energy Efficiency
- More Renewable energies

**How? How much? Which kind of RE?**

.....

# Tunisian Electricity System Modeling

## Modelling Tool: Open Source Energy Modelling Systems “OSeMOSYS”

- A bottom-up, dynamic and linear optimisation model
- Aims to **calculate the lowest net present cost of an energy system to meet given demands.**
- The demands for energy are met by **technologies competing against each other** and defined by a set of economic, technical and environmental parameters and policy goals
- It is used for long-term energy planning by developed and developing economies’ researchers and governments
- The mathematical language used for simulating the model is **Gnu Math-Prog using the solver GLPK.**

# Tunisian Electricity System Modeling

	rate of activity $\leq$ capacity potential	production $\geq$ demand + use + trade	RE production $\leq$ RE demand * target	technology emissions + exogenous emissions $\leq$ annual emissions limit	Demand RM * RM $\leq$ Capacity in RM	rates of production by technology vs online capacity reserves vs. rates of production by technology
total discounted cost = sum discounted costs + emissions penalty - salvage value	total capacity = residual capacity + accumulated new capacity	<ul style="list-style-type: none"> <li>rate of activity * input activity ratio = use</li> <li>rate of activity * output activity ratio = production</li> </ul>	<ul style="list-style-type: none"> <li>RE production = tag * technology production</li> <li>RE demand = tag * rate of demand</li> </ul>	<ul style="list-style-type: none"> <li>emission activity ratio * technology activity = technology emissions</li> </ul>	<ul style="list-style-type: none"> <li>demand needing RM = production rate * RM fuel</li> <li>total capacity * RM technologies = capacities in RM</li> </ul>	<ul style="list-style-type: none"> <li>load partialisation = online capacity - rate of production by technology</li> <li>...</li> </ul>

## Objective function:

Estimate the lowest net present value (NPV) cost of an energy system to meet given demand(s) for energy or energy services taking into consideration the  $Y, r, t, f, e$

$$\text{Min total NPV cost} = \text{Min} \sum_{r,y} \text{Total discounted cost}_{r,y}$$

## Decision Variables:

Rate of activity ( $r, l, t, m, y$ )

New capacity ( $r, t, y$ )

Online capacity ( $r, t, y$ )

# Tunisian Electricity System Modeling

## Main assumptions

<b>Time domain</b>	<b>2010 to 2030</b>
<b>Time slices</b>	16, weekdays and weekends, day and night for three seasons and Ramadhan
<b>Existing technologies</b>	NG fired Steam PPs, CCGTs, OCGTs (large and small capacities), wind turbines, hydro power plants, decentralised PV and onshore interconnections
<b>Future technologies</b>	CCGTs, OCGTs (large capacities), wind turbines, decentralised PV, Centralised PV, CSP, PSH, and onshore & offshore interconnections
<b>Considered Scenarii</b>	BAU scenario: <ul style="list-style-type: none"><li>• 5% of electricity generation by 2030</li></ul> RE scenario: <ul style="list-style-type: none"><li>• 30% of renewables by 2030</li></ul>

# Main Results

## Capacities Shares

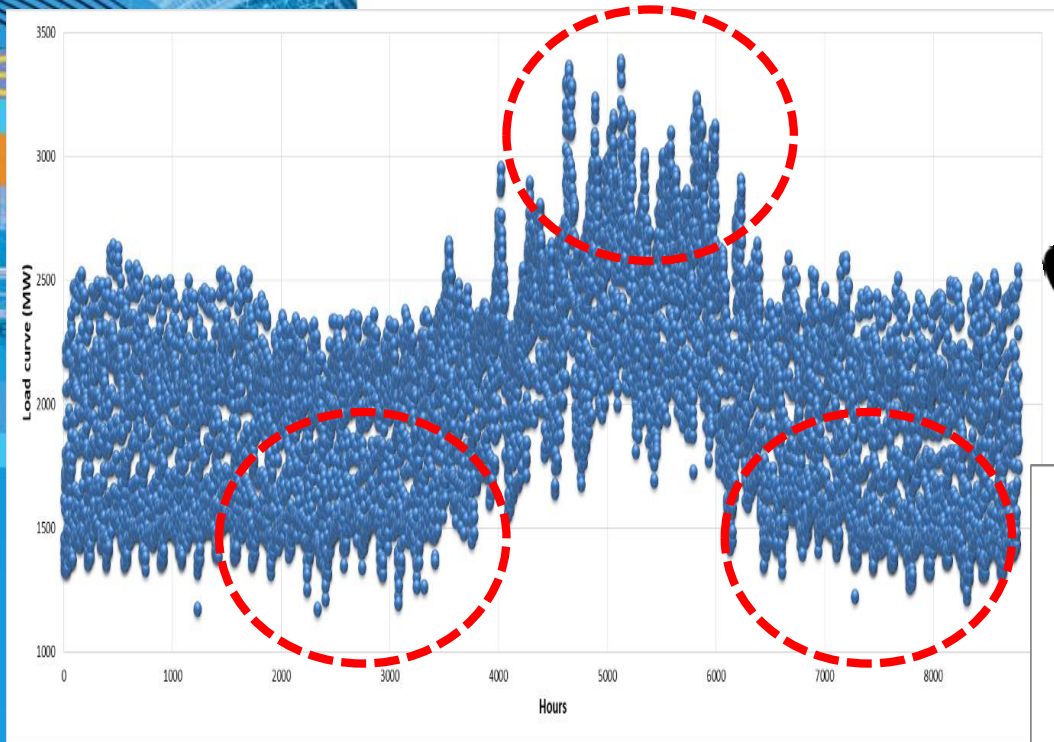

BAU Scenario

RE Scenario

# Main Results

Annual load curve in 2016

Evolution of daily profiles

# Main Results

## Impact of Energy Efficiency

Amongst energy efficiency actions:

- Peak clipping: reducing the demand during peak periods through scheduled outages 😊
  - Load shedding: cutting electricity supply by zone during a period to manage the demand and avoid blackouts, due to the incremental peak or variability of RES ☹️
- ➔ Load shedding could be associated to peak clipping, if it is targeted, well planned, and programmed in advance
- Peak clipping : decreasing the peak + avoiding the system operator from using costly technologies, low efficiency and polluting technologies

System reliability

# Main Results

## Impact of Energy Efficiency

- System reliability: the rate of the satisfaction of demand of all customers
- System reliability could be associated to the Loss-of-Load Probability (LOLP)

$$\forall_{r,l,f,y} \text{SystemReliability}_{r,f,y} = \Pr (S \geq D) \text{ or } \text{SystemReliability}_{r,f,y} = 1 - \text{LOLP}_{r,f,y}$$

~~$$\forall_{r,l,f,y} \text{production}_{r,l,f,y} \geq \text{demand}_{r,l,f,y} + \text{use}_{r,l,f,y}$$~~

$$\forall_{r,l,f,y} \text{production}_{r,l,f,y} \geq \text{demand}_{r,l,f,y} \times (\text{SystemReliability}_{r,f,y}) + \text{use}_{r,l,f,y}$$

# Main Results

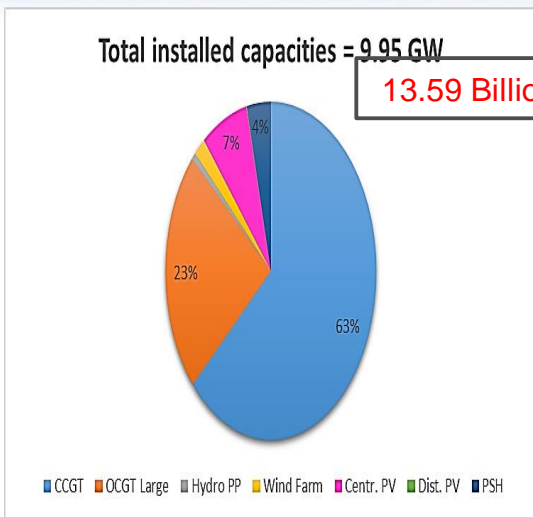

## Impact of Energy Efficiency

Reliability= 99%

Reliability= 98%

Reliability= 97%

BAU scenario

RE scenario

Impacts of "Planned" reliability on investments by 2030 – BAU vs. RE scenario

# Conclusions

- The decrease of the reliability of the power system by 1% has allowed decreasing the costs of RE scenario by 0.12 billion 2010 USD and the costs of the BAU by 0.14 billion 2010 USD;
- The total cost of RE scenario at a reliability of 97% is equal to the cost of the BAU scenario at 99%, i.e. 13.58 billion 2010 USD. Achieving 30% of RE in the electricity mix with 97% of power system reliability is as costly as a BAU scenario with 99% reliability.
- The 2% decrease in system reliability while integrating RE could be assessed through EE actions such as peak clipping.

- Decreasing system reliability could be seen as an energy efficiency action boosting the implementation of RES in the power system.
- Such actions could be integrated alongside RE Government's objectives through outages tariffs or smart meters, etc.

Thank you for your attention
